Design techniques in Carry Select Adder using Parallel prefix adder for improved switching energy

Abstract. A new architecture of Carry select adder has been proposed with improved switching energy using parallel prefix adder. The conventional Carry select adder is the use of two Ripple Carry Adder (RCA) and a multiplexer. The findings in this work are the replacement of one RCA block by Brent Kung adder and the other RCA block by excess-1 converter. Simulation results show that the proposed Carry select adder is proved to have improved switching energy when compared with the other adders in 45nm CMOS process.

Streszczenie. Zaproponowano nową architekturę sumatora Carry Select z ulepszoną energią przełączania przy użyciu równoległego sumatora prefiksów. Konwencjonalny dodatek Carry Select wykorzystuje dwa Ripple Carry Adder (RCA) i multiplekser. Wyniki tej pracy to zastąpienie jednego bloku RCA sumatorem Brenta Kunga, a drugiego bloku RCA konwerterem nadmiaru-1. Wyniki symulacji pokazują, że proponowany sumator Carry Select ma lepszą energię przełączania w porównaniu z innymi układami w procesie 45 nm CMOS. Keywords: Brent Kung Adder, Carry generation, Carry Select Adder, Generation stage, Parallel prefix adders, Pre processing stage **Słowa kluczowe:** sumator Carry Select, RCA – Rip[ple Carry Adder

Introduction

The digital design depends on the three aspects. They are area, power and delay. In a conventional or standardized adder, the sum bit relies upon the sum generated out of the preceding bit and carry generated is circulated to the upcoming bit position[1-2]. Due to the presence of generation of the carry, there occurs a limitation in speed causing a major effect in this field. Ripple carry adder comprises of full adder blocks. Therefore, addition operation is performed with the usage of full adders in order to generate sum and carry. As the carry ripples throughout all the stages, it is termed as Ripple Carry Adder (RCA).

A conventional or regular CSLA is designed with a couple of multiplexer and ripple carry adders[2-3]. The ripple carry adder is designed to provide sum and carry outputs. The multiplexer determines the final sum and carryout bits when $C_{\rm in}$ is known. Addition can be performed in RCA by considering $C_{\rm in}$ =0 or $C_{\rm in}$ =1. However, in the conventional CSLA the area occupied was large, as it required two ripple carry adders to generate sum and carry. To improve the switching energy, conventional CSLA is replaced with the proposed CSLA structure by using parallel prefix adders to achieve less area, power and delay.

Hence there is a need to modify high speed adder by replacing RCA with parallel adder configuration. As reported in the literature survey, it is noticed that the performance of Brent Kung adder was better and utilizes less area. The Brent Kung adder can be used in multiplier and other data path elements.

Conventional Technique

The Carry Select Adder usually comprised of two n-bit parallel adders (ripple carry adders) and a multiplexer. Addition is organized with two n-bit parallel adders to calculate the sum and carry. The carry input is given as logic'0' and logic '1' to the RCA. The Multiplexer determines the sum and carry output based on the known carry input. Among all the adders, RCA has smaller area with more propagation delay. The Carry Skip Adder (CSA) is designed with a scheme to reduce the propagation delay. The Carry Look Ahead Adder (CLA) eliminates the ripple effect. Hence, CLA speed is more when compared with RCA. The carry bit ripples throughout the adder block in the RCA. Therefore, CSLA provides a solution for this

linear dependency by using two carry-in inputs i.e., Cin=0 and Cin=1 and generate the result in a more advanced method. The final result can be received by multiplexer when the correct Cin value is known. The circuit diagram of conventional CSLA is shown in Fig.1. The CSLA is used in numerous digital applications to avoid the propagation delay.

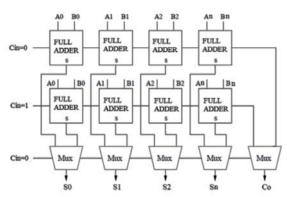

Fig. 1. Circuit diagram of Conventional CSLA [2] Carry Select Adder

CSA generally comprises of 2, n-bit parallel adders and a multiplexer. The multiplexer determines the ouput (sum and carry) when the Cin value is known.

Full Adder

Full Adder is an adder which comprises of A, B and C_{in} as input and two outputs (sum,Cout). Fig.2 shows the basic block of full adder.

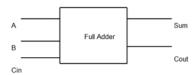

Fig. 2 Basic block of Full Adder

The full adder diagram is shown in Fig.3.

(1) Sum = A Xor B Xor C_{in} (2) Carry = A.B + B. C_{in} + A. C_{in}

When the condition C_{in}=0,

(3) Sum = A Xor B

(4) Carry = AB

When the condition C_{in}=1,

- (5) Sum = NOT (A Xor B)
- (6) Carry = A Or B

Modified Csla Using Bk Adder

As discussed earlier, in the conventional or in the standardized CSLA the performance is not good as it has a pair of n-bit parallel adders to generate sum and carry bits [4-7]. To overcome this difficulty, conventional CSLA is replaced to modified CSLA structure by using parallel prefix adders to achieve less area, power and delay.

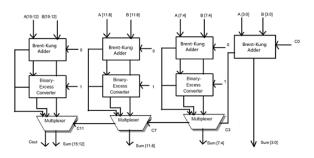

Fig.5 Block Diagram of CSLA with Brent-Kung Adder Brent Kung Adder

Parallel Prefix Adder

Parallel prefix adder is a fast adder which is used for increasing the speed in processor to perform addition

operation[8-9]. Parallel prefix adder is similar to Carry Look Ahead Adder. Parallel prefix adders are designed for achieving high efficiency in many applications. The 3-main stages in parallel prefix adder include Pre-processing stage, Carry generation stage and Post processing stage [10-13]. The block diagram of CSLA with Brent-Kung Adder is shown in Fig. 5

Among the various architectures of parallel prefix adder, Brent Kung adder is better in its performance. It also comprises of n number of input and output stages. The area occupied in Brent Kung Adder is very less when compared with other parallel prefix adders. The propagating as well as generating cells is less in Brent Kung adder. Hence, BK adder can be designed for high speed computing applications. Fig.6 shows the post processing circuit. The primary stage is the pre-processing unit in which comprises of generate as well as propagate pointers that are received from the inputs. In the secondary stage the outputs of primary stage are fed as input and carry signals are generated. The ultimate stage is the post processing unit where the final result is attained from the secondary stage using carry signal and propagate a signal from primary stage.

Fig.6 Block Diagram of Brent Kung Adder

Pre Processing Stage

The primary stage inputs are Ax and Bx and the outputs are Gx and Px.

- (7) Gx=Ax . Bx
- (8) Px = Ax Xor Bx

Carry Generation Stage

In carry generation stage, all the carry signals are obtained. This stage has 3 logic cells. They are Black-Cell, Gray-Cell, and Buffer Cell. The circuit may vary according to the number of inputs.

- (9) Gx:y=Gx:z+Px:zGz-1:y
- (10) Px:y = Px:zPz-1:y

Post Processing Stage

This is the ultimate unit in which the XOR function is employed between the propagate pointer and the output of carry pointer received from the secondary stage. The architecture of Brent-Kung adder is shown in Fig.7

- (11) Sx = Px XOR Cx-1
- (12) Cx = Gx + Px Cx-1 or Cx = Gx

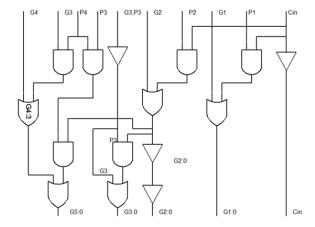

Fig. 7 Architecture of Brent Kung Adder

Binary to Excess-1 Converter

The modified CSLA is attained by changing the RCA with excess-1 converter and BK Adder. Binary to Excess-1 converter is very simple because it uses less logic and also provides area reduction when compared to RCA [14]. Table 4 shows the truth table for BEC.Fig.8 shows the BEC Circuit Diagram.

The equations for BEC conversion are given below:

(13) E0 = Not (B0)

(14) E1 = B0 Xor B1

(15) E2 = B2 Xor (B0 . B1)

(16) E3 = B3 Xor (B0 . B1 . B2)

Results and Discussion

The conventional CSLA and the modified CSLA using BK Adder are designed using Verilog. Simulation and synthesis of adders are done using Geneus Tool in Cadence . The output waveforms of conventional CSLA, RCA, BEC, BK adder and modified BK adder were

obtained. Fig. 9 shows the schematic of modified CSLA. Fig. 10 shows the output waveform of CSLA. Fig. 11,12,13 shows the power,delay and area obtained for CSLA

Fig. 12 Output Delay

Table 5 shows the Performance comparison of th modified CSLA. The BK adder is used to compute the carry for each stages. The carry bit and the propagate bit of the next stage is used to compute the sum of the current stage.

The power consumption of the proposed CSLA is very less when compared with the other types of adders. Simulation and Synthesis report shows that the designed CSLA reported improved power delay product in comparison with the other conventional adders.

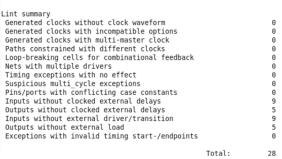

Fig. 13 Output Delay

Table 5 Performace comparision of the Conventional adders with the proposed CSLA adder.

CSLA STRUCTURE	Area (µm²)	Total Power (μW)	Delay (ns)	Power Delay Product (PDP) fJ
	669	33.56	1.36	45.64
CONVENTIONAL	978	54.29	1.76	95.50
CSLA	941	32	1.61	51.52
	634	61	2.45	149.40
	931	49.28	1.62	79.80
MODIFIED CSLA	842	29	1.45	42.05
	474	57	2.21	125.97
This Work	331	985.537nW	28	27.59

Conclusion

In this work, it is concluded that the modified CSLA structure has more advantage in terms of area reduction, power and rapid speed is attained through the parallel prefix structure. Therefore it can be determined that modified CSLA using BK adder is much better in terms of power and power delay product (switching energy) when related to other adder circuits.

Acknowledement

The authors were thankful to the management of Karunya Institute of Technology & Sciences and VLSI Lab/Department of ECE for providing software and support towards this research work.
